

Doro - Audit legal requirements - iOS (2024)

Facts about the audit

- Client: Doro AB Niclas Rosenqvist, niclas.rosenqvist@doro.com Audit performed by: Per Edwall & Christer Janzon Our reference: Lennart Engelhardt lennart.engelhardt@funka.com App: DoroHemmaDev app for iOS, Doorbell hardware from customer Not audited content: All PDF-documents and third-party solutions Time of audit: 2024.07.02 - 2024.07.19 Equipment used: • iPhone 11 & iPhone Xr iOS 17.5.1
 - VoiceOver screen reader
 - External keyboard

Background

Funka has performed an audit in order to monitor the status of

compliance

with the Web Accessibility Directive.

Each success criteria is scored as follows:

• No errors found. The interface adequately meets the requirement. This may mean that the solution is very good, or acceptable. There may be room for improvement.

• No errors found but can be improved. Either the interface has a few problems in need of fixing (not a consistent error, more a result of carelessness or misunderstandings), or the interface has problems in parts that are beyond the scope of the audit, or problems that for one reason or another needs to be discussed with the client.

• Fail. The interface has consistent, clear accessibility issues that need to be rectified.

• Not applicable. The interface does not contain the kind of solution the requirement applies to, or the requirement has not been scored for one reason or another.

Funka's methodology is developed in close collaboration with the disability movement and everything we recommend has been tested in a real-world setting. Our operation is based on the international guidelines for accessibility, Web Content Accessibility Guidelines, WCAG 2.2. WCAG 2.2 was launched on October, 2023.

Funka's depth of experience in accessibility and user testing with users with varying abilities and needs, with and without assistive technologies, show that neither the EN or WCAG standards are enough to ensure the accessibility for all users. Because of this, Funka has developed our own requirement to supplement these standards.

Funka has, being named a Lead Translation Organisation, been tasked by the W3C carried out the authorized translation of WCAG 2.0 to Swedish, and has been tasked with the translation of WCAG 2.1 as well.

Funka's specialists are since 2008 involved in the efforts to create the EN301549 standard on behalf of the European Commission. We are appointed experts in the ETSI Special Task Force tasked with harmonizing the EN standard with WCAG 2.1 and ensure that the requirements are applicable on documents and

applications. We are elected technical experts in the Swedish Standards Institute's committee representing Sweden in the standardization efforts. We lead the group of experts that provide support to the member states of the EU and the commission in the transition period for the Web Accessibility Directive and the development of a supervision methodology and accessibility statement.

Audit summary

Many things work very well in the app, and we believe you considered accessibility during development. However, there are still accessibility issues that need to be addressed, as some user groups may face challenges using the app. Assessments will be a fail even if there is only one issue, though we have seen good examples of accessibility in other parts of the app.

While some problems may be extensive and require significant effort to resolve, there are also smaller issues that present opportunities for improvement.

For some user groups, such as screen reader users, visually impaired users, and keyboard users, certain views may be challenging.

For screen reader users, some items are not presented with their role, meaning users do not know what type of item they are interacting with. This is particularly true for links, buttons and forms. Forms and error messages often cause difficulties for this user group, and this is the case here too. We find it very difficult to believe that a screen reader user will even be able to create an account due to the requirement to be able to enter a code, even if the quality of your forms is very good.

Users with impaired vision are likely to face major problems because the text does not support Dynamic Type, but also because the contrast requirements are not met.

Users who rely on an external keyboard will most likely encounter issues, mainly because some functions cannot be focused on and activated with an external keyboard.

The app should also be usable in both portrait and landscape views, but it is currently locked to portrait view only.

Funka International AB, Stockholm 2024.07.19

Comments

General

GE80: Help functions are consistently placed

Background

If you offer help functions such, as contact details, chat systems or self-help guides, these must be consistently placed in the interface. This way, users can always find help in the same place.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.2 - 3.2.6 Consistent Help (A)

GE90: Pages and functions are described consistently

Background

The website should be consistent in how it describes different functions, links and areas. For example: if one page says 'e-services', do not call the same services 'self-service' on another page.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.1 - 3.2.4 (AA) WCAG 2.0 - 3.2.4 (AA) WCAG 2.2 - 3.2.4 Consistent Identification (AA) EN 301 549 - 9.3.2.4 No errors found

Not applicable

Html & css

HC30: The HTML code does not contain critical errors

Background

There are several different standards in HTML. Each standard has its own rules for which elements and attributes may be used. Some examples of standards are HTML4, HTML5, XHTML 1.0 and XHTML 1.1.

Funka always recommends HTML5 as standard because it has increased accessibility support compared to older standards. Something to keep in mind is that HTML5 is a living standard that is supplemented with elements and attributes on an ongoing basis. For this reason, you shold make sure that the new elements and attributes are supported by both browsers and assistive devices before using them.

For browsers, assistive devices, and other tools to interpret the code correctly, they need to know which standard the current page is encoded in. Specify this at the top of the code on all html pages of the website with a !DOCTYPE declaration. !DOCTYPE is declared as follows in html5:

<!DOCTYPE html>

Follow the chosen standard

However, it is not enough to simply declare a certain standard, it is important to actually follow it. The standard has been created so that developers of, for example, browsers, code libraries, websites, and aids have a common source to look at to ensure that the content is presented optimally.

Robust code

The W3C mentions in WCAG four important specifications that the code must follow in order to be considered robust:

- Complete start- and end tags.
- Do not use the same id value on two different elements on the same page.
- Do not specify the same attribute twice in the same element (eg two alt attributes in the same img element).

Not applicable

• Nest the elements according to the standard.

If there are deviations from these specifications, the interface is not considered robust enough to meet the requirements of WCAG. Other types of deviations from the specifications are not considered to result in as major accessibility issues, but Funka recommends that there should be no deviations from the specifications at all.

There are several different tools to validate the code against the selected standard. W3C has a HTML validator which can be accessed at the address: http://validator.w3.org/

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 4.1.1 (A) WCAG 2.1 - 4.1.1 (A) WCAG 2.2 - 4.1.1 Parsing (Obsolete and removed) (A) EN 301 549 - 9.4.1.1

HC80: The reading order of the content is logical

Fail

Background

When you control layout and presentation using CSS, you can position different areas visually regardless of their exact location in the HTML code.

However, assistive technology read the website's HTML code from top to bottom. This means that assistive technology presents the content in the same order as the code, not in the visual order determined by the CSS code. For this reason the reading order of the content must be logical and reflect the visual order.

Funka recommends that the user should be able to use the content even when the CSS files are blocked. This enables the user to control how the information is presented.

The fact that it is possible to use does not mean that it is an optimal user experience. For example, it may mean that the menu is presented twice or shows several levels before the user selects something. Of course, such problems must be minimised, but sometimes they may be unavoidable, for example to achieve good functionality when the interface is built responsively.

Apps

The reading order with a screen reader in an app may differ based on the operating system.

iOS

The reading order with VoiceOver is determined on the visual interface. The order is left to right, up to down. Developers can customise the order to match the reading order.

Android

With TalkBack, the reading order follows the order of the code in the same way as in a browser. Again, the order may not match the reading order, so developers can set their own order.

Comment

We have found views where the reading order isn't logical.

In the view below, the reading order is incorrect. The last thing that happens in the focus order is that the form fields themselves are read out with VoiceOver. To be logical, the order should go from top to bottom and from left to right.

In the next example, the reading order is not directly incorrect but time consuming. A screen reader user has to jump between four different elements in a single item. The way it should work, each row in the list should only get focus once and then all the text should be included, not the name of the icons.

To do

- Make sure that all functions can be controlled with VoiceOver activated.
- Also make sure that the reading order in the views is logical.

Links to guidelines

WCAG 2.0 - 1.3.2 (A) WCAG 2.1 - 1.3.2 (A) WCAG 2.2 - 1.3.2 Meaningful Sequence (A) EN 301 549 - 9.1.3.2

Flexibility of the interface

RD10: All information can be accessed and used regardless of screen size

Background

It is usually impossible to fully predict where, when and how the user will choose to use the interface. For this reason you should never remove the ability to access all information and functionality in the interface even if it is displayed on a small screen. However, feel free to modify the presentation to save space, such as using collapsible areas to hide parts of text.

We usually divide screen widths into three main categories:

- Large screen width regular computers and laptops with or without an external screen.
- Medium screen width tablets or computers that use a smaller resolution.
- Small screens such as mobile phones.

There may be a need for a more detailed division, depending on the interface. It is important that it works well across the spectrum, from small mobiles to large screens, in both portrait and landscape view.

The interface must work down to a width equivalent to 320 CSS pixels and a height equivalent to 256 CSS pixels.

320 x 256 CSS pixels is equivalent to a viewport of 1280 x 1024 CSS pixels at 400% zoom. You can test this yourself by setting the browser window width to 1280 CSS pixels, the height to 1024 CSS pixels, and zooming to 400%.

Row lengths

A recommendation for line lengths for paragraphs is that they should be between 50 and 80 characters long including spaces in all screen sizes.

There are different principles and methods that can be used to build responsive solutions. If line lengths and areas adapt to the window width, that's good, but the most important thing is that the interface is usable from smaller screens to very wide screens, and that the presentation order is logical regardless of screen width. This also includes ensuring that line lengths are sufficient to accommodate long words.

 No errors found but can be improved

Navigation

As soon as visible navigation collapses into a so-called hamburger menu, the interface generally becomes more difficult to use. A recommendation is therefore to try to maintain navigation where level one is visible in as many screen sizes as possible.

If you simplify so that not all information or services can be accessed in one screen size, you must offer the user the possibility to get to the regular interface.

Comment

We have not had the opportunity to test the app on a device other than the iPhone device on which the analysis is based. However, we recommend that you test the app on different iPhone and iPad devices with different screen sizes.

To do

• Keep in mind that an iPad-adapted version can give the users a better experience.

Links to guidelines

WCAG 2.0 - 1.4.8 (AAA) WCAG 2.1 - 1.4.8 (AAA) WCAG 2.2 - 1.4.8 Visual Presentation (AAA) WCAG 2.1 - 1.4.10 (AA) WCAG 2.2 - 1.4.10 Reflow (AA) EN 301 549 - 9.1.4.10

RD30: The interface is viewable and usable without forcing the user to scroll in more than one direction

Background

It is impossible to predict how a user will choose to view or use an interface. For this reason the interface must be responsive. It should adapt to the screen width chosen by the user, without losing content or functionality.

If content or functions do not fit on the user's screen, scrolling is only allowed in the vertical or horizontal direction, not in both directions at the same time. The interface must, under this condition, work from at least 320 pixels wide or 256 pixels high.

Sometimes exceptions may be necessary for specific content, such as tables, charts or illustrations.

No errors found

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.1 - 1.4.10 (AA) WCAG 2.2 - 1.4.10 Reflow (AA) EN 301 549 - 9.1.4.10

RD40: The website is fully legible and usable when zoomed 200%

× Fail

Background

Some browsers offer the possibility of adapting the text size if the texts are inserted with relative sizes (e.g. em and %). This setting has been overshadowed these days by the more widespread zoom function that magnifies everything, regardless of what dimension units the text is in.

Although websites no longer have to be built using relative dimensions, it is important that text does not become difficult to read and that functions are difficult to use if the user has changed the text size settings in the browser. If the website is designed with relative sizes, it also means this needs to be done in a way that does not distort the way the pages are displayed in the browser.

Users must also be able to zoom the website up to 200% without texts overlapping each other and becoming difficult to read or functions becoming difficult to use. This does not just apply to large screens with HD resolution but also to smaller screens and smartphones.

Bear in mind that a responsive user interface should adapt when the user zooms. In other words, even when you zoom in on a responsive user interface, you should be able to access all functions and all the information. Naturally, there is a limit where too small a screen with too great a zoom will no longer work, but when the user reaches this point, the user should still be able to continue to zoom even if this can mean having to scroll sideways to read all the text.

You will ensure users zoom in on mobile devices with the following code in the page header:

<meta name="viewport" content="user-scalable=yes">

The content attribute can contain many more sub-attributes and associated values

to control the presentation on different screens. Using the maximum-scale subattribute can impair user scope to zoom even when you have stated userscalable="yes. We recommend you avoid using maximum-scale. To date, we have not experienced any problems with other sub-attributes.

Although a specific solution for how to manage to zoom and change window size must be customised from case to case, here are a few brief recommendations for normal web interfaces:

• The website should adapt automatically to the window size, but it is important to insert mechanisms that prevent line lengths longer than 70 characters, including spaces or being so short that whole words cannot be displayed.

• If the user changes the text zoom function in the browser, this should not mean that the content cannot be read or functions are not able to be used.

- Zooming via the browser zoom function should work up to at least 200%.
- If the window or text size is reduced, you should still be able to read the text and use the functions.

Comment

When we increase the text size to the equivalent of 200%, the text is generally enlarged well in most places. However, we have encountered a few different issues.

In the example images below, there are some cases where the text is truncated or disappears in buttons because the area doesn't expand when the text itself is enlarged.

Another issue is that some texts don't support Dynamic Type and aren't affected by text scaling. See two example views below.

FAQ

Doro Hemma Doorbell FAQ

- Vad ingår i Doro Hemma Doorbell boxen? Behöver jag köpa något annat?
- Kan jag ha mer än en ringklocka i mitt hem som är ansluten till min dörrklocka?
- Kan jag ha mer än en dörrklocka(ytterdel) ansluten till mitt hem?
- Kan jag använda min Doro Hemma Doorbell med min iPhone/iPad?
- + Kan jag använda dörrklockan på flera enheter, som min iPhone och min iPad?
- Vad är den förväntade batteritiden för dörrklockan mellan laddningarna?
- Kommer jag att informeras när batteriet börjar ta slut?
- + Hur laddar jag dörrklockan?
- + Hur kan jag se batterievivån på min dörrklocka?
- + Behöver jag internet hemma

If you want to test text scaling by yourself, you increase the text size in the system settings. Go to Settings > Accessibility and select Display & Text Size. Tap Larger Text for larger font options. Dragging the slider to step 9 of 12 is equivalent to 200%.

To do

• Make sure that the text's container is flexible so that it adapts when the text is enlarged.

• All texts should support Dynamic Type and be affected by text scaling.

Links to guidelines

WCAG 2.0 - 1.4.4 (AA) WCAG 2.1 - 1.4.4 (AA) WCAG 2.2 - 1.4.4 Resize Text (AA) WCAG 2.0 - 1.4.8 (AAA) WCAG 2.1 - 1.4.8 (AAA) WCAG 2.2 - 1.4.8 Visual Presentation (AAA) EN 301 549 - 9.1.4.4

RD60: Users can access all content and use all functions regardless of screen orientation

Fail

Background

When content is presented to a user, it should not be locked to a portrait or landscape view. Videos and tables should be responsive and viewable in any orientation, unless there are specific reasons. Full-screen videos often require the device to have a landscape orientation, but should be playable in portrait view as well.

In various situations the user may need to use mobile phones or tablets in a specific orientation, for example if the device is mounted to a holder on a wheelchair. The orientation of the interface should then be adapted to the user's conditions. As a result, the experience is not always optimal, but it should work. An example of this is viewing videos in portrait mode.

This requirement does not apply to changes in content or features due to screen size, only to screen orientation.

Comment

The app is locked to portrait mode only, which fails this checkpoint. To meet Success Criterion 1.3.4 Orientation in WCAG 2.2, the app must not restrict its view and operation to only a single display orientation, such as portrait mode.

To do

• Enable to use the app in both portrait and landscape mode.

Links to guidelines <u>WCAG 2.1 - 1.3.4 (AA)</u> <u>WCAG 2.2 - 1.3.4 Orientation (AA)</u> <u>EN 301 549 - 9.1.3.4</u>

Navigation & links

NL20: The interface can be controlled by keyboard on both desktop and mobile

Fail

Background

There are different ways to control a computer or smartphone. There are different solutions for moving the mouse cursor, clicking, and entering text. By enabling the interface to be controlled by keyboard, mouse and touchscreen, the user can choose the solution they prefer.

For some users, there are no options. Some cannot use a regular keyboard and must navigate with the mouse. Other users cannot use any kind of mouse or touchscreen and must navigate with the keyboard.

A basic principle in WCAG is that it should be possible to control the interface using only a keyboard, whether it is on a large or small screen. This must work if you are to be considered compliant with WCAG.

Exceptions to this requirment can be made if, for example, it concerns a function that could not reasonably be made to work independently of the input device.

Avoid common problems

Avoid adding features that require the user to click or hover over different areas, such as menus that require the user to hover with the mouse.

Avoid lists that refresh the page or move the focus as soon as the value in the list changes. These types of solutions create major problems especially for people who have to navigate with the keyboard, but also for people with reduced precision or who are sitting in busy environments.

Be careful about changing interaction patterns that the user is familiar with. For example, users who navigate with the keyboard are used to using the tab key to move between links and form items. If the user is suddenly expected to use the arrow keys instead, many users will have problems.

You should also bear in mind that the combination of responsive design and zoom

can result in mobile viewing even for desktop users. It is then essential that it works independently of the input device also in mobile view.

Comment

It works well in many views when navigating with an external keyboard. We can control most switch buttons and form objects.

However, there are also views where it doesn't work as it should. In the images below, we marked areas we couldn't reach with either the Tab or arrow keys with an external keyboard.

In the image below, the whole area receives focus but it's not possible to activate the button in it.

10:46

.... 🛜 78

To do

• Make sure all essential functionality can be controlled with an external keyboard.

• Remember that elements without a role (link/button) will not be possible to activate with a keyboard.

• Continue testing by yourself by connecting an external keyboard to your device and navigating in the app.

NL30: Keyboard navigation follows a logical order

Background

A user navigating with a keyboard cannot control the order in the same way as a user navigating with a mouse or touchscreen. The navigation order is instead controlled by the website.

This is often only related to the tab order. The most common way to jump between items with the keyboard is to press the tab key repeatedly. This moves the focus between the different links and form objects on the website.

The tab order is normally the same as the order of the content in the code. Each time the user presses the tab key, they jump from one link or form object to the next.

The attribute tabindex can be used to control the tab order. There may be occasional reasons to use this attribute, for example to help prevent an object from gaining focus, but all objects that the user tabs to should be in a logical order in the structure of the page. In this case, there is no need for a tabindex to control the order.

Tabindex works as follows:

• **Tabindex = 0** adds inactive objects, such as a div, to the tab order where they are naturally located in the page structure. Funka's recommendation is to primarily use HTML elements that are naturally interactive (such as links and buttons). However, in some situations there may be a need to allow the user to tab to other objects, in which case tabindex="0" should be used.

• Tabindex > 0 prioritises the items and changes the navigation order so that

 No errors found but can be improved

it does not follow the structure of the page. The order will be from the lowest number upwards. After the user reaches the item with the highest tabindex entry, the tab order continues from the first interactive item in the code.

• **Tabindex = -1** means that the object cannot be tabbed to, but that it can be given focus through scripts. Used, for example, to script focus on an error message so that it is conveyed to assistive technology users.

In some functions, the user navigates with other keys as well, such as the arrow key to move focus between different radio buttons. It is important that other keyboard navigation has a logical sequence as well.

Comment

The order is mostly logical and we have only found one place where the order is illogical and that is under 'Hjälp', see below. The order is backwards, which isn't a big problem but should still be changed.

.... 穼 <mark>997</mark>

In the example below, the order is a bit jumpy. When selecting a country, it doesn't work with the arrow keys. If the user then uses the Tab key, they first end up on the back button at the top, then the container and then the focus is on the first option 'None' in the select list. If it instead worked with the arrow keys it would be more logical and some unnecessary navigation steps could be skipped.

We assess this requirement with no errors found but can be improved.

To do

• We recommend correcting the order under 'Hjälp' and ensuring it's possible to navigate in your select lists with the arrow keys.

Links to guidelines

WCAG 2.0 - 2.4.3 (A) WCAG 2.1 - 2.4.3 (A) WCAG 2.2 - 2.4.3 Focus Order (A) EN 301 549 - 9.2.4.3

NL40: Focus is clearly displayed when users navigate with the keyboard

Background

When users navigate with the keyboard on a web page or in a function, it must be visually clear where the focus is. When you tab through the menu, the menu option that is currently in focus can be highlighted with a frame or by inverting the colours. In some functions where you can navigate with the arrow keys, the same recommendation applies: The object that is in focus should be clearly delineated visually.

Hidden links and shortcuts should also be highlighted and displayed visually when they receive focus with keyboard navigation.

The focus indicator should be visible. For example, it can be a slightly thicker frame, a thicker underline, an inversion of colours or a background plate that appears.

Comment

Objects that can receive focus with an external keyboard always have some kind of focus indicator, which is good. However, sometimes the indicator is very weak, which can cause problems for users with impaired vision or for those who have difficulty recognising weak contrasts.

In the images below we use the default settings for focus indication and these two elements only get a slight colour change in the text and we recommend improving it. No errors found but can be improved

WCAG 2.0 - 2.4.7 (AA) WCAG 2.1 - 2.4.7 (AA) WCAG 2.2 - 2.4.7 Focus Visible (AA) EN 301 549 - 9.2.4.7

1

partially visible. The recommendation is that the entire object is visible. Common areas that may obscure focusable objects are headers, navigation elements, and modals that do not scroll with the rest of the page but remain in their position,

NL50 : When an object receives keyboard focus, it is

For sighted users navigating the interface with a keyboard, it is crucial to understand where the focus is. Therefore, it is important that the object with keyboard focus is always visible to users. This applies to all screen sizes.

To meet this requirement, the object with keyboard focus should be at least

known as "sticky".

Background

at least partially visible

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.2 - 2.4.11 Focus Not Obscured (Minimum) (AA)

NL60: There are shortcuts to facilitate keyboard navigation

Background

For users who rely on keyboard navigation, it can be inconvenient to tab through the entire menu structure on every page. When users have found the page they were looking for, they are interested in the content.

To make it easier for these users, shortcuts should be provided on the pages. The most common shortcut leads directly to the content of the page, bypassing the navigation. But in different contexts it may also be appropriate to have links back to the top of the page, or to different menu groups on the page.

These types of shortcuts are created by inserting links that lead to an element further down the page. Visually, these types of links should be hidden until a user gets keyboard focus on them.

Links to content are created like regular links but with the # character followed by the target's id value. The most common is to link to the content area or the initial heading.

No errors found

Not applicable

The link can look like this:

```
<a href="#content">
Skip to main content
</a>
```

The target, which in this example is a heading, can look like this:

```
<main>
<h1 id="content">
Content main heading
</h1>
</main>
```

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 2.4.1 (A) WCAG 2.1 - 2.4.1 (A) WCAG 2.2 - 2.4.1 Bypass Blocks (A) EN 301 549 - 9.2.4.1

NL70: Keyboard shortcuts are not only activated with alpha-numerical keys

Background

Many users control the user interface entirely or partly with keyboard navigation and keyboard shortcuts. For some users with mobility disabilities or severe visual impairments, the keyboard is the primary form of controlling the interface. With voice control, users may use voice commands to then convert these into keyboard commands. For example, a person that controls the interface via the voice can say "tab" to move to the next link. This guides the assistive technology to send the keyboard command "tab" to the interface.

It's important that the keyboard shortcuts and regular shortcuts are not based on numbers, characters, or symbols only, since this may cause users navigating with Not applicable

the voice or keyboard to accidentally activate functions. Examples of this may be that information is deleted, or contacts are being called by mistake by the user. When using this kind of keyboard shortcut, the following must be taken into consideration:

- There's a mechanism to turn off keyboard shortcuts.
- Keyboard shortcuts can be changed to be controlled by another key.
- The keyboard shortcut is only possible to use when the controlling object is in focus.

The accesskey attribute is not covered by this requirement since that kind of keyboard shortcut is activated by pressing one key and one of the Alt, Shift, Control or Option keys simultaneously.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

<u>WCAG 2.1 - 2.1.4 (A)</u> <u>WCAG 2.2 - 2.1.4 Character Key Shortcuts (A)</u> <u>EN 301 549 - 9.2.1.4</u>

NL90: Clicks can be cancelled or the user has an option to undo the click

Background

A click consists of two parts, adown event, and an up event. The down event occurs when the user pushes their mouse button, or their finger down on the screen. The up event is when the button is released, or the finger is lifted from the screen.

When a user navigates through an interface by clicking with a mouse cursor or a touchscreen, unintended events sometimes occur - the user simply clicks or presses in the wrong place.

To reduce such problems: avoid functionality that happens when the user clicks down. Instead, let the functionality be activated when the user releases the mouse button.

In some cases this is not possible, such as for a piano app, where the user plays

No errors found

the piano by clicking down on the keys.

If an event must be activated by a down event, there should be a chance for the user to undo the event if possible. An example of this is many on-screen mobile phone keyboards. By resting the finger on a letter, a number of less common letters appear (example: if you rest your finger over the A key, you can type á, â or). If the user lets go of the screen without making a selection, no character is typed.

NL100: Content and functions are usable without complicated gestures

Background

Users with reduced mobility in their hands and fingers have difficulty controlling the precision that is often required to navigate an interface. There are also input techniques where difficult gestures, such as eye tracking, cannot be performed. For example, it is very difficult or impossible to perform gestures that require more than one touch point with eye tracking, or to achieve a motion path with a switch. For this reason, it is important to create interfaces based on the simplest possible gestures. There should be alternative ways that allow these users to easily control the interface without difficult gestures. Users with a head mouse or eye tracker are not helped by keyboard shortcuts via an on-screen keyboard. Instead, gestures should be complemented by buttons that the user can press. Examples of one type of interface based on gestures are server-based maps, where the user can zoom in and out by pinching together or apart with two fingers.

where the user can zoom in and out by pinching together or apart with two fingers. Another gesture is to use two fingers to move the geographical area displayed on the map horizontally or vertically.

Alternatively, for users with motor disabilities, the zoom function can be controlled by buttons: plus to zoom in and minus to zoom out. Right, left, up and down buttons allow the user to tilt and pan the map to change the geographical area.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

NL105: Features can be used without dragging motions

Background

Users with reduced mobility may have difficulty controlling certain interfaces where a dragging motion is required.

Additionally, dragging motions cannot be performed with certain techniques, such as eye tracking.

If a solution requires the user to perform a dragging motion, there must be an alternative solution, such as buttons.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.2 - 2.5.7 Dragging Movements (AA)

NL110: Visible descriptions of clickable objects are described in a similar way through hidden descriptions in the code

No errors found

Background

There are many techniques for describing interactive objects. For common input fields, a visible label is often used in connection with the input field. It is usually enough if the label is inserted correctly, but in some situations, visually hidden descriptions inserted with, for example, the aria-label attribute is also used. There may be many reasons for adding a visually hidden description. For example, a user who doesn't see the interface may be in need of an extended description of the field.

When using hidden descriptions it is important that they describe what is displayed visually. An object with a label containing the text "Buy" or "Read more", or an image illustrating the function of the object, should begin with the same text in the visually hidden label or description. A button with the description "Buy ticket" should, for example, also be initiated with the wording "Buy ticket" in the aria-label or aria-labelledby attributes.

Users with cognitive or severe mobility disabilities may use their voice to control

No errors found

the interface, rather than using the keyboard or pointing device to navigate. When visually visible and hidden labels match, voice control also works well and is predictable.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.1 - 2.5.3 (A) WCAG 2.2 - 2.5.3 Label in Name (A) EN 301 549 - 9.2.5.3

NL120: Functionality that is activated through motion can be disabled and controlled in a different way

Not applicable

Background

Mobile devices can for example use accelerometers, gyroscopes and cameras as an input method or to perform a function.

For users with mobility disabilities, it is problematic when functions in an interface are based on motion. This assumes that the user can move their device freely, which is not possible for example for users who have their device mounted on their wheelchair.

For this reason, interfaces should, whenever possible, be controlled by buttons, links and other objects as an alternative to movement.

There are exceptions for functions that rely on movement to operate, such as pedometers and spirit levels.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.1 - 2.5.4 (A) WCAG 2.2 - 2.5.4 Motion Actuation (A) EN 301 549 - 9.2.5.4

NL160: Target size meet the minimum size requirement.

Background

Adequately sized clickable areas are important for all of us to hit the right spot, but for some users, it's especially crucial. This is the case, for example, when using a touchscreen, having impaired precision, or being in distracting environments, such as on a train.

As important as the size of clickable areas is the distance between them. The issue for users is often not small clickable areas but rather that they are placed too closely together. If two clickable objects are placed next to each other, either the distance between them should be sufficiently large, or the clickable areas should extend relatively far in each direction so that the user doesn't risk hitting the wrong area.

The minimum requirement for the size of clickable areas is at least 24 by 24 CSS pixels. This means that all sides of the clickable area should be at least 24 CSS pixels long. There are some exceptions to this requirement, such as links within body text or if the clickable areas are sufficiently spaced apart.

Example of a clickable area that does not meet the minimum size requirement:

The rounded corners result in a square with a side length of 24 CSS pixels not fitting entirely inside the clickable area. If the distance to other clickable areas is sufficiently large, the example above could still be approved.

Example of a clickable area that meets the minimum size requirement:

 No errors found but can be improved

A square with a side length of 24 CSS pixels fits entirely inside the clickable area.

Comment

Here, we cannot see the exact size of the different clickable elements in iOS, but when we compare the border that VoiceOver shows, they appear to be similar to those on Android and are then approved.

If you are more interested in this, we refer to the Android analysis in this criterion.

To do

• Strive for clickable areas to be 48dp x 48dp in size.

Links to guidelines

WCAG 2.2 - 2.5.8 Target Size (Minimum) (A)

NL170: Link groups and information areas are grouped

Background

To make it easier for the user to identify groups of objects, it is important that there is a clear grouping in the code, for example, by grouping menus using bulleted lists. The menu links will then be presented as a coherent group in assistive technologies used by severely visually impaired users. In menus where submenus are expanded, nested lists should be used (lists within lists). The hierarchical structure will then be perceivable by severely visually impaired users. In HTML5, there is an element called nav that should be used to declare the navigation on the page. The element should enclose both the main menu and submenu, or two different nav elements should be used to declare the main menu

and submenu, respectively. The element can also be used for a larger menu in the page footer. This is how it is used:

```
<nav> ... Menu links ... </nav>
```

Landmarks

WAI-ARIA defines different landmarks that are also used to mark up different types of content on a page. These will add more structure for users that cannot see the interface.

If you are building with HTML5 you should use the elements available in HTML5 firstly. You can also insert landmarks but avoid using the element nav and role="navigation" at the same time, this can cause problems for screen readers in certain cases.

How to insert landmarks:

```
<div role="search"> ... Search function ... </div>
```

Use the following landmarks where relevant:

- role="search", which marks the search function
- role="main" or <main>, which marks the main content on the page
- role="complementary", used for content that is complementary to the main content on the page. This includes all types of "related information", i.e. the type of content that typically is placed in the right-hand column on the page.

• role="banner" or <header>, used for the page header

• role="contentinfo" or <footer>, used for identifying information, such as copyright information, navigation links, and privacy statements. This section is commonly called the page footer.

There are several landmarks:

• role="application", used for areas with application-like interactions, for instance, a text editor. Avoid using this landmark unless you have very strong reasons for using it.

• role="form", avoid this as it does not add anything for users at the moment. Information about WAI-ARIA (W3C website).

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

NL190: The target of links is clearly stated in context

× Fail

Background

When link texts are clearly formulated, it will help guide all users to find the right link. A clearly formulated link is also a necessity to enable severely visually impaired users and certain users with cognitive disabilities to find the information they are looking for. Links must therefore provide clear information as to which pages they lead to and what type of content these pages contain.

Severely visually impaired users find it impossible to get a visual overview of the page. This means that they cannot identify the links located on the page at a glance and what blocks of text they are linked to. Severely visually impaired users have to navigate their way around the page instead of exploring the page with the support of their assistive technology, a screen reader.

A screen reader only presents the information the user is focusing on. If the focus is on a link, only the link will be read, not the text around it. The user cannot visually connect the link to the adjacent text. This means that the link itself must provide all relevant information as to where it leads.

Many tools also include a function that takes the links out of their context and presents them in a separate link list. This speeds up navigation and enables the user to quickly find specific links like "Log in" or "Shopping basket". When a link is taken out of context, it does not help the user if the text next to the link says where it leads, but the target of the link must be clear from the link text itself. Links that say "Read more" or "Click here" are therefore not sufficient.

Linked images must provide all relevant information about the link in the alt text (sometimes called "description" or "tooltip" in different authoring tools).

For email links, it is important that the actual email address is stated in the link

text, plus information about the recipient, for instance, the recipient's role and/or name. Stating the email address is important to enabling a user who does not wish to email straight away to copy the address to use at a later time.

Title text

Do not insert any title text (sometimes called "description" or "tooltip") in links. The link text should give the user all relevant information about the link. Some websites used to add a title text to the link that would be shown when the user hovered over the link, but this solution cannot be utilized by users who use a keyboard or touchscreen navigation.

Links are understandable in their context

WCAG on level A requires links to be understandable on their own or through their programmatically determined context. That means that it should be possible to understand the link together with any text in the same HTML element. That could mean placing a text and the link in the same paragraph element or list

element.

The easiest way to meet this requirement is, however, what's easiest for the users; to write link texts that make it easy to understand the link's purpose regardless of context.

Comment

We can see that there are clickable items take the user from the app to the web view. In some cases these elements look like a link and are even presented as a link to screen readers, but sometimes they do not.

In the image below we see an email link that is presented as a link and VoiceOver reads out the name and mentions that it is a link, see image below. It works just as it should.

When we go to the next link "Läs vår sekretesspolicy här", we are not told that it is a link, or that it is clickable. Only the name is read out even though visually it looks a link.

In this case, we don't think it will be a problem because it can be understood as clickable since the link text itself mentions it. However, clickable components should be coded so that this information is given to a screen reader.

Adress: **Doro AB** Jorgen Kocksgatan 1B SE-211 20 Malmö Sverige

Telefon: +46 (0)46-280 50 00

Epost: sales@doro.com

The same problem, with elements that look like links but aren't coded as such, applies to the next example image.

1	2:38		🗟 🚺
< 1	Tillbaka	Villkor	
	Användarkonto	D	^
	C Link ToC	about user	
	Fjänster		^
	🛛 Link to th	ne home service	<u>ToC</u>
	Anslutna enhe	ter	~

Link to the home service ToC

Another problem concerns links that are coded inconsistently. There are links that are coded as links, links that don't appear to be clickable, and others that are coded as buttons. They all look the same but behave differently.

14:01	:	II 🗢 100
🕻 Tillbaka	Integritetpolicy	
Marknads Datainsa marknad	sföring mling och Isföringsgodkännande givande för marknadsföring

	Medgivande för marknadsföring, Button	

We also want to mention that the view where we can create an account or choose to log in, it is possible to get focus on "Manage account" with iOS but it is not possible on our Android mobile.

To do

• Ensure that all clickable items are correctly coded so that a screen reader user recognises them as links/buttons, not just by name.

• Ensure that objects that take the user from the app to a browser, or web view, are presented as links to screen reader users.

• Remember that elements without a role will not be possible to activate with a keyboard.

• Strive to give all links an icon so that they are visually recognisable regardless of their purpose or destination.

• Also, ensure that icons, that is part of a link or button, dont get focus.

Links to guidelines

WCAG 2.0 - 2.4.4 (A) WCAG 2.1 - 2.4.4 (A) WCAG 2.2 - 2.4.4 Link Purpose (In Context) (A) EN 301 549 - 9.2.4.4

NL360: When the same menu or link collection is shown on different pages, the sorting order should be consistent, unless users would find the order illogical

Not applicable

Background

Do not change the sort order in the listing of links, tools, or menus on different pages. The same menu or link collection should be presented in the same relative order throughout the website unless it would not be perceived as illogical by the user.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

Colours & presentation

CP10: The text contrast between foreground and background is adequate

× Fail

Background

To enable visitors to access the content in a plain and clear way, it is important that there are good contrasts (actually light contrast) between the text and background. On a contrast scale that goes from 1:1 (no difference) to 21:1 (black on white), the contrast ratio should be at a minimum of 4.5:1.

For larger text, such as headings, a contrast ratio of at least 3:1 is enough. Though our recommendation is to keep the contrast ratio at least at 4.5:1, for the text to be clear for as many users as possible.

24 pixels or less, or 18.5 pixels bold or less	Larger than 24 pixels, or larger than 18.5 pixels bold	Graphical objects, clickable surfaces, form fields, diagrams, and similar.
Approve	Approve	

Approve

Fail

Also, keep in mind that the contrast requirement applies to text that appears in videos, such as nameplates and subtitles.

Tools for measuring contrasts

To measure contrasts, a complex formula that is available on the WCAG website is used:

<u>The formula for contrasts (WCAG 2.1 website), opens in a new window</u> If you don't want to calculate this yourself, WAI recommends the tool "Colour Contrast Analyser", which can be downloaded free from the TPGi website: <u>Colour Contrast Analyser (TPGi website), opens in a new window</u>

Comment

Overall, the contrasts in the app are good. However, some texts against their adjacent colours don't meet the minimum contrast ratio of 4.5:1.

The problem exists in different types of elements, both clickable and plain text. see images below.

	 Fail (UI components and graphical objects)

In the last example, we are unsure about the exact text size. If the text size is more than 24dp, then the required contrast ratio is 3:1. Otherwise, the required contrast ratio is 4.5:1, just like in the previous examples.

We evaluate this criteria as failed.

To do

• Go through all your components and make sure all text has a contrast ratio of at least 4.5:1 to its adjacent colors.

Links to guidelines

WCAG 2.0 - 1.4.3 (AA) WCAG 2.1 - 1.4.3 (AA) WCAG 2.2 - 1.4.3 Contrast (Minimum) (AA) WCAG 2.2 - 1.4.6 Contrast (Enhanced) (AAA) EN 301 549 - 9.1.4.3

CP20: Graphical objects conveying information, illustrations and videos have adequate contrasts

Fail

Background

The contrasts in illustrations, charts, images, icons, and videos must be sufficient. The user should be able to see and interpret the graphic information even in poor lighting conditions and with a lighter visual impairment. Therefore, strive for as good contrasts as possible. The contrast ratio in this type of material must be at least 3:1 according to WCAG. The ratio refers to the colour of the graphic motive against the background.

An exception to the requirement is when the object is supplemented with text.

Comment

We found that the contrast of graphical objects in the app is good. However, we found one graphic object that does not meet the minimum contrast ratio of 3:1. What we mean can be seen in the example image below and the reason is that it is an indicator that the area is clickable. At moment it has a contrast ratio of 1.3:1 but needs to achieve 3:1 to be acceptable.

We evaluate this criterion as failed.

To do

- Increase the contrast ratio of the icon to be at least 3:1.
- Make sure all graphical objects that convey information, such as icons, have a contrast ratio of at least 3:1 in all views.

Links to guidelines

WCAG 2.1 - 1.4.11 (AA) WCAG 2.2 - 1.4.11 Non-text Contrast (AA) EN 301 549 - 9.1.4.11

CP25: Visual indication of clickable objects and adjacent colours have a contrast of, at least, 3.0:1

Background

It is not only text that needs to have sufficient contrast and be clear in an interface. Interactive objects such as buttons, links, and form fields should be clearly distinguishable even in poor lighting conditions. In order for users with lighter visual impairments to be able to distinguish interface components, it is important that frames around such objects have good contrasts against adjacent colours. The contrast value should be at least 3.0:1.

The contrast requirement between the frame and background colour applies in several situations: when users mark a clickable object or form object, when an object is in focus when the user navigates with the keyboard, or when the user has selected a specific object.

The contrast requirement does not apply to components whose design has not been adapted, as their layout is determined by the settings of the user's browser. It also does not apply to inactive components.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.1 - 1.4.11 (AA) WCAG 2.2 - 1.4.11 Non-text Contrast (AA) EN 301 549 - 9.1.4.11

CP35: Understandability is not dependent on the user's ability to perceive colour

No errors found

Background

Colour can often be a clear and functional way to convey information. Red colour often indicates warning texts and error messages, blue colour is strongly associated with links.

However, you should not rely on colour alone, as many people have limited colour vision. A general estimate is that between 5% and 9% of the world's population

No errors found

have some form of limitation in colour vision (source: Colour Blindness Awareness, 2023).

In addition, people who does not have limited colour vision may still have problems perceiving different colours in different situations. For example, it is often difficult to perceive colour changes in running text on a mobile phone or tablet outside on a sunny day.

Make information understandable independent of colour

In order to ensure that a user's ability to perceive colour is not a deciding factor in their ability to understand the interface, you must complement with at least one more way to convey the information.

Examples:

- links can be underlined or supplemented with an icon.
- buttons in different colours can be provided with text
- diagrams can be presented with different line types.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.4.1 (A) WCAG 2.1 - 1.4.1 (A) WCAG 2.2 - 1.4.1 Use of Color (A) EN 301 549 - 9.1.4.1

CP50: The interface works well with custom settings for text

Not applicable

Background

For users with dyslexia or visual impairments, it is important to be able to change the way texts are styled. There are various browser plugins that allow you to control the size and font, as well as the spacing between lines, words, characters and paragraphs.

It must be possible to change the text spacing without making functions inaccessible, and without hiding or cutting off the content. The result does not

have to be perfect, but making changes must be possible to do in the user's browser and must not be blocked.

The user must be able to change the spacing according to these dimensions:

- Line height (line spacing) to at least 1.5 times the font size;
- Spacing following paragraphs to at least 2 times the font size.
- Letter spacing (tracking) to at least 0.12 times the font size;
- Word spacing to at least 0.16 times the font size;

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.1 - 1.4.12 (AA) WCAG 2.2 - 1.4.12 Text Spacing (AA) EN 301 549 - 9.1.4.12

CP60: The website is presented without disturbing screen flicker, moving and flashing elements that cannot be switched off

No errors found

Background

Just as a disturbing text background can be distracting, interface movements can also divert the user's attention, making it more difficult to concentrate on text. Movements, blinking and flickering should be avoided for this reason. If you wish to have this, it should either stop automatically within 5 seconds, or there should be a noticeable way to stop the movement.

Please note that anything that flashes more than 3 times per second is never allowed.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 2.2.2 (A) WCAG 2.0 - 2.3.1 (A)

CP70: The pages have unique and relevant page titles

Background

The page title is important, and is one of the first things some users meet. The page title is also used as text when the user bookmarks the page, and search engines use the page title when indexing pages.

It is therefore important that every page on your website have unique page titles that describes the page's content and function clearly.

We recommend that you first specify the unique content of the page in the title, and then the name of the website.

In HTML it might look like this:

<title>Funka WCAG guide - Funka</title>

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 2.4.2 (A) WCAG 2.1 - 2.4.2 (A) WCAG 2.2 - 2.4.2 Page Titled (A) EN 301 549 - 9.2.4.2

Not applicable

Structure & formatting

ST40: Headings reflect the content

Background

The heading is the first thing the user reads. Therefore, it is important that the heading provides relevant information about the associated text. The heading should contain one or more of the main keywords of the body text.

Both main headings and subheadings should be descriptive and concise. The heading should describe the content that follows.

If there are area headings in the page's framework, they must briefly and accuratlely describe area's topic. Try to use precise headings such as "E-services", "Brochures and in-depth information", or "Contact".

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 2.4.6 (AA) WCAG 2.1 - 2.4.6 (AA) WCAG 2.2 - 2.4.6 Headings and Labels (AA) EN 301 549 - 9.2.4.6

ST60: Text that visually function as a heading is coded as a heading

Background

The headings are one of the first things the user sees and reads on a new page. The importance of having good headings is therefore extremely great in order to reach out with the information. However, not all users are able to see the headings. Some users are dependent on assistive technologies to access information. In order to enable assistive technologies to understand what are headings on a page, as well as render these to the user, they need to be correctly coded with the h elements.

Several things are of importance, but a basic premise is that what looks like and, therefore, visually functions as headings are also coded with correct heading

No errors found

× Fail

elements.

In HTML, headings are coded with the h1, h2, h3, h4, h5 and h6 elements. The number indicates the level. It is also possible to code headings with wai-aria. Then you add the role="heading" attribute to the text and specify the level with the aria-level attribute. However, we do not recommend this since the support among assistive technologies is not 100%, and this increases the risk of problems.

There is one exception to this requirement. If you have headings that appear as soon as the page loads and are located before the content's main heading in the structure, they should not be coded as headings. An example of this is a visual heading above the left menu on a web page where the navigation is located before the main content in the structure. However, if you have a drop-down menu that only appears when the user clicks a button or link, and it has visual headings, then they should be coded as headings.

Comment

Many texts that function as headings are not coded as headings in the app. When the texts receive focus with the VoiceOver screenreader, the text is presented, but not that it is a heading. To meet this checkpoint, all texts that function as headings must be presented as such.

Below are two examples:

11:25		::!! 중 100)
🕻 Tillbaka	Skapa konto	
Ange din e	-postadress	
- Ny e-postadr	ess	
per.edwa	ll@funka.com	\otimes

per.edwa	ll@funka.com	\otimes
E-post korr	rekt	
Avbr	t (Näeta
		Nusia
	Steg 1 av 7	
	Skapa konto	

To do

• All texts that function as headings must be presented as headings to a screen reader user.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A)

WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

ST80: The heading structure begins with a main heading

Background

The heading elements should form a logical structure. This means the first heading should be coded as an h1 heading. Example:

```
<h1>Main heading</h1>
<h2>Subheading</h2>
<h3>Heading level 3</h3>
<h3>Heading level 3</h3>
<h2>Subheading</h2>
```

Comment

There are techniques supported from version 15.0 in iOS to add levels to headings.

In some web views, headings have levels but most headings don't. But since it is possible to add it, we recommend that you review the possibility of adding levels to all headings and that the heading structure begins with a main heading. We assess this checkpoint with no errors found but can be improved.

To do

• Review the possibility of adding levels to all headings and that the heading structure begins with a main heading.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1 No errors found but can be improved

ST90: The heading structure is logical and represents the hierarchy of the content

Background

All pages should have a main heading that provides the user with information about the text and gives an opportunity to the user to choose whether to start reading or not. Any text longer than a couple of paragraphs should also have subheadings. Subheadings are usually required to make the text comprehensible and clear, both for experienced and inexperienced readers. They can also be of great help to people with reading difficulties.

Subheadings also facilitate skim-reading, especially for people who use reading aids. Many aids present the headings as a table of contents of the text, and also make it possible to jump between headings. In this way, the user does not have to read through the entire text to reach the information of interest.

The heading structure must be logical and reflect the structure of the page's content. Begin all pages with a main heading (the h1 element) at the top of the content. Subsequently, all headings should come in a hierarchically correct order that reflects the structure of the content. Keep in mind that the number should not reflect how important the heading is, but how it relates to other headings. Is it a subheading to the previous heading, or should it be on the same level?

Comment

As we mention under ST80, it's possible from version 15.0 in iOS to add levels to headings.

It's mostly missing in the app but in the example below the heading 'Mitt konto' is a level 3 heading. To be more logical it should be a level 2 heading if the main heading 'Konto' was level 1. No errors found but can be improved

10:14		::!! ? 100
=	Konto	
Mitt konto		
🤶 Min Pro	ofil	
Namn	Per Edwall	1
E-post	per.edwall@funka.com	1
Land	Sweden	1
Lösenord	****	/
	Ta bort användare	
_		
L	Mitt konto, Heading level 3	

This checkpoint is also assessed with no errors found but can be improved.

To do

• Review the possibility of adding heading levels. Then make sure that headings are structured according to how they relate to each other and that heading levels are not skipped.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

ST120: Lists are correctly coded and used in a correct manner

No errors found

Background

Some information needs to be entered into lists. This includes enumerations, definition lists, and descriptions of different steps in a process.

To insert these as lists in the code, the elements available in HTML for this purpose should be used. This is a prerequisite for assisitive technologies to be able to interpret and present them as correct lists to the user.

To start a bulleted list the element ul is used, to start a numbered list the element ol is used. Each list element is then created with the element li.

Lists can also be used to structure the menu. By putting the menu in a nested list, you can convey the hierarchy of the menu in a basic way even to users who cannot see it.

Example:

```
<a href="b.hmtl">Breakfast</a>
<a href="l.html">Lunch</a>
<a href="m.html">Meat</a>
<a href="m.html">Vegetarian</a>
```

For definition lists, the dl element is used to start the list, the dt element to indicate

the term to be defined, and the dd element to provide its description. Example:

```
<dl>
<dd>Sweden</dt>
<dd>Stockholm</dd>
<dd>Stockholm</dd>
<dd>Stockholm</dd>
<dt>Norway</dt>
<dd>Oslo</dd>
</dl>
</dl>
```

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

ST180: Paragraphs are created correctly using the p element

No errors found

Background

To insert text paragraphs on a page, the p element should be used. This makes the document easier to skim-read with assistive technologies. The user can then jump from paragraph to paragraph. This is especially important in legal texts where the different paragraphs must be distinguishable from each other. Do not use the br or hr elements to separate text paragraphs.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A)

ST200: Quotes are marked up using q or blockquote

Not applicable

Background

Mark up longer quotes with the blockquote element.

Note that blockquote must be used only for quotes. Visually, the element creates an indent in the text, but do not use the element only to create visual indents.

Use the q element to highlight and format shorter quotes.

In both blockquote and q elements, the cite attribute should be used to indicate a source in the form of a URL if such a source exists.

Example:

<blockquote
cite="http://www.bbc.com/weather/prognosis_071224.html">

There is a 50-50 chance of snow in northern Europe for Christmas. However, this is based on the low pressure system now over the British Isles steering northwards.

</blockquote>

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Images

IM10: Text is presented as text, not as images of text

Background

Images are, in many ways, a better way of communicating information than plain text. Images can help illustrate complex connections and difficult concepts. Images also help in that they break up the text and make the user experience the text less intense and difficult.

Images of text

In other words, images should be used where appropriate, but they should not be used to represent text. When text is used in the content, in menus, or other parts of the pages on the website, it should be added as plain text. Images of text usually create large accessibility problems.

When images are zoomed, each image pixel becomes larger. Text, on the other hand, is inserted as vectors, which means that each character is made up of more pixels when the text is zoomed. The difference is that the image of text becomes pixelated and is often perceived as blurrier, while the normal text remains sharp. This becomes especially apparent in magnifying tools. The two images below illustrate this. The first represents an image of text which is created with pixel graphics, and the second is an image of real text which is created with vector graphics. It's the same text size, and we've zoomed in 300%.

Text som bild Text som text

Another problem with images of text is that the text in an image cannot be adapted by tools for dyslexics, nor can it be copied, and that is something some of the assistive tools for this group require. Even if you add an alt text to the image, it is not certain that a tool for dyslexics can perceive this.

No errors found

Exceptions

In certain situations, there can be reasons to use text in an image, for example, in organization charts or different types of flowcharts where the text needs to be part of the image.

When text is used in such images, we recommend it to be at least twice the size of the normal text on the website (as the text in the image cannot be zoomed in a good way by browsers and assistive tools). At the same time, the contrasts must be good, and the image must contain an alt text.

If the text cannot communicate all the information the image shows, there must either be a detailed description inserted via a detailed text description or a link next to the image. If it is an organization chart, the organization's different departments can be described in text under the image. Use headings and lists to structure the information as clearly as possible.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

WCAG 2.0 - 1.4.5 (AA) WCAG 2.1 - 1.4.5 (AA) WCAG 2.2 - 1.4.5 Images of Text (AA) WCAG 2.2 - 1.4.9 Images of Text (No Exception) (AAA) EN 301 549 - 9.1.4.5

IM30: Equivalent text descriptions are present for all meaningful graphical elements on the website

× Fail

Background

In order for assistive tools to render the content of images to the user, the images must be provided with an alternative description. This is usually done using the alt attribute (which can be called a tooltip or description in various authoring tools). The alternative description should briefly describe the subject or purpose of the image. The more important the image is for the page and the understanding, the more detailed the description needs to be.

The alt text should be kept to less than 150 characters, but sometimes this is not enough to describe all the information in the image. Then the alt text must briefly

state what the image shows and refer to a longer description or corresponding information. For example:

"Graph of population growth in Sweden. See table after the image". As a principle, all images that contain information, illustrations, photographs, icons, image buttons, image links, and similar, are meaningful graphic objects. Non-meaningful graphic objects include hyphens, empty spaces, coloured background tiles, and similar. These kinds of images should primarily be inserted with CSS.

Linked images require a little extra thought. If you have a link that only consists of an image, the image's alt text must primarily reflect the target of the link. If you have a link that contains both an image and a text, then the link description will consist of the link text and the image's alt text. Depending on the situation, you may need to have an empty alt text. For example, it's just annoying to hear: *Printer Print*, if you have a print link with an icon.

If you have a form and use the input type="image", this must have an alt text that explains the function of the object. However, note that it is usually better to use input types that are adapted for the purpose, for example, it is better to use the input type="submit" or a button element for buttons, rather than an image. If you use the figure and figcaption elements, the image must have an alt text. Example:

```
<figure>
<img ... alt="Sweden year 1790" />
<figcaption>
The image shows Sweden's distribution in 1790...
</figcaption>
</figure>
```

Comment

There are quite a few meaningful graphical elements in the app. Unlike the Android audit, we were not able to focus on hardly any images at all with the VoiceOver screen reader.

However, two kinds of images which could receive focus were the progress bars below. In the first example, the text description isn't descriptive enough as it only says '45 dot 00'.

11:33			::!! \$ <mark>999</mark>
🕻 Tillbaka	Skapa	konto	
Välj land			
Land Swed	en		•
Föregåe	nde	 ✓ 	Nästa
			
	Steg 3	3 av 7 ot 00	

In the second example though, it says 'Progress, 17 percent' which is good. We recommend having the same description in the first example.

15:20		::!! ? 100
🕻 Tillbaka 🛛 Ins	tallation av dörrklocl	ka
mot ytan. 5. Följ instru att sätta fa montering	ktionerna i videon ast dörrklockans Jsplatta.	nedan för
Föregåe	nde N Steg 1 av 6	ästa
	Förlopp, 17 percent	

To do

• Ensure that all meaningful graphical elements in the app have equivalent text descriptions.

• Non-meaningful images and icons should be hidden and not focusable.

Links to guidelines WCAG 2.0 - 1.1.1 (A) WCAG 2.1 - 1.1.1 (A) WCAG 2.2 - 1.1.1 Non-text Content (A) EN 301 549 - 9.1.1.1

IM60: Image maps have text descriptions for both links and images

- Not applicable

Background

Image maps are images that contain clickable areas. There are two types of image maps: client-based and server-based.

A client-based image map is a regular image where parts of the image are defined as linked areas.

A server-based image map is an image where you can click anywhere. The coordinates are sent to the server, which in turn determines what is sent back to the browser. This technology is used in many zoomable map services such as Google Maps.

Accessible client-based image maps

For users with assistive technologies, client-based image maps work best. It is relatively easy to ensure that all areas have an appropriate description.

The image used for the image map should have a brief description of what the image depicts, just like any meaningful image.

The different clickable areas (area elements) must be described in the title attribute, but can also be complemented with a description in the alt attribute.

You can also complement with plain text links to the same pages that the links in the image lead to.

This is what the code for a simple client-based map might look like. Here we have chosen to use both alt text and title text in the clickable areas, because the support for both attributes varies in the area element:

```
<img src="map.gif" usemap="#map" alt="Map of Europe">
<map id="map" name="Map">
<area shape="poly"
```

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Forms

FS10: Forms are coded correctly with form elements

Background

It is important that all parts of a form are inserted as correct objects designated for forms, otherwise, they will not be presented together with other parts of the form when being presented through an assistive tool. In some cases, buttons appear to be created as linked images (A elements) instead of correct buttons in the form. When this is the case, they will not be listed with other objects in the form, and this makes it difficult for some users to submit the form.

It is also important that the right type of element is used. Instead of using, for instance, checkboxes, and adding a script that prevents anything other than one checkbox from being checked at a time, radio buttons should be used.

There are several new types of objects designated for forms in HTML5. These have many advantages for users, especially on mobile devices where the keyboard can adapt to the type of information that is to be entered. An example of how different input types generate different keyboards on mobile is shown below.

```
<label for="postort">postort</label></label type="number" id="postort">
```

```
<label for="postnummer">Postnummer</label><input type="text" id="postnummer">
```

× Fail

Postort	Posto	ort	
1			
Postnummer	Postn	nummer	
			Klar
qwertyuic	på 12	3 4 5 6 7	890
asdfghjkl	öä - /	:;()kr	& @ "
☆ z x c v b n m) × #+=	. , ? !	′ 🗵
	Sök ABC	€ Q mellanslag	ОК
123 🌐 🖉 mellanslag			

Comment

There are form objects not presented as form objects to VoiceOver users. This makes it difficult for them to understand what they are interacting with, which needs to be clarified.

One example is the popup button below. When we interact with it there are many navigation steps.

First, we receive focus on the label, see below.

11:30		:!!! 중 100)
🕻 Tillbaka	Skapa ko	onto
Välj land		
Land Swed	en	•
Föregåe	nde	✓ Nästa
	Steg 3 av	7
	Land, Form sta	art

Then the flag image, see below.

11:30		::!! ? 100
🕻 Tillbaka	Skapa konto	
Välj land		
- Land Sweden	1	•
Föregåend	e) 🗸	Nästa
	Steg 3 av 7	
	Sweden, Image	

Finally, we receive focus on the popup button but there is no information that it is even clickable, see below. The optimal solution would be to have just one navigation step saying something like 'Land, Sweden selected, Popup button'.

11:30	::!! \$ @}
	oa konto
Välj land	
Sweden	•
Föregående	✓ Nästa
St	eg 3 av 7
	Sweden

The same applies to the options, see the two navigation steps below.

11:32	:!!! 중 明
< Tillbaka Skapa konto	
Välj land	
Sweden	•
None	
Andorra	
Austria	
Belgium	
Steg 3 av 7	
None, Image	

11:32	:!!! 중 995
< Tillbaka Skapa konto	
Välj land	
Sweden	•
None	
Andorra	
Austria	
Belgium	
0	
Steg 3 av 7	

The final examples below are similar. The form objects are not presented as popup buttons and are not even clickable.

13:52	11	∻ 100
≡	Hantera detta hem	
	ne	
Medler	nmar	?
t 2	Medlemmar som lagts till	,
07	Öppna väntande inbjudni	•
\square	음 Bjud in användare	\supset
	🔓 Läggas till i ett nytt hem	\supset
FÄRGT	EMA	
	Green	·
0	Återställ alla heminställning	ar
	FÄRGTEMA, Green	

To do

• Ensure form objects are presented as such so it's clear to VoiceOver users what they are interacting with.

• Strive to have everything in the same container so there is only one navigation step for each form object.

FS50: There are labeled instructions that describe how to complete forms

× Fail

Background

When the user chooses or enters information, there must be clues and instructions that clearly indicate what to choose or enter. The instructions should also contain information about specific formats and other important information that the user needs in order to enter information correctly.

Mandatory fields

In some cases, the users must fill certain inputs to complete a form. It must be clearly distinguishable which fields are mandatory and which fields are not. To only use an asterisk (*) does not indicate for all users that an input field is mandatory - it should appear in text what the icon means. At Funka, we recommend that if a majority of the input fields are mandatory, you should instead write in which that are voluntarily filled, please see the example below.

Deltagarinformation

Namn

Titel/ Arbetsområde (valfri)

E-post

Comment

In general, there are good and descriptive labels when users are supposed to enter information in different form objects.

However, below is a form object missing a label. There is an instruction above the text fields but as a visible label is missing we still believe that this can lead to problems for sighted users but especially for VoiceOver users. As seen below, when focusing on the first text input with VoiceOver, the only given information is that it is a text field but there is no name.

11:35	배 송 983			
🕻 Tillbaka	Skapa konto

	Steg 5 av 7			
l	Text field, Double tap to edit.			

To do

• Make sure all form objects have a label. Also, make sure it's tied to the form object, read more under FS60.

Links to guidelines

WCAG 2.0 - 3.3.2 (A) WCAG 2.1 - 3.3.2 (A)

FS60: Labels are linked to corresponding form object

× Fail

Background

Instructional text is a text that states what the user should enter in a certain field, the significance of checkboxes/radio buttons, or what the user should choose in a list. These instructional texts are often clearly positioned visually close to the form object (text field/checkbox/radio button/list/button) in the question, which means users who can see the page and read the text are clearly informed of the form object's purpose.

In order for this to work for users who need various tools to access the information, there must be a clear connection in the code between the instructional text and the form object. This is achieved with the label element. Use label-element to insert all instructional texts. The label element must also be correctly connected to the respective form object with the attribute for that pointing to the form object ID.

In addition to the instructional text, the label element should also include possible clarification and a possible error message bound to the form object. Please note that you should only have 1 label element for each form object.

If the interface is coded in HTML5 the form field should be labeled with what type of field it concerns.

```
<form action="http://www.funka.com/survey" method="post">
```

```
<label for="namn">Namn</label>
<input type="text" name="namn" id="namn" />
<label for="country">Land</label>
<select name="selectCountry" id="country">
<option disabled>Välj</option>
<option>Norge</option>
<option>Sverige</option>
</select>
```

```
<fieldset>
<legend class="hidden">Godkänn</legend>
<label for="yes">
<input type="radio" name="accept" id="yes">Ja, jag
godkänner</label>
<label for="no">
<input type="radio" name="accept" id="no">Nej, jag
godkänner inte</label>
</fieldset>
<label for="comments">Kommentar</label>
</fieldset>
<label for="comments" id="comments">
</textarea name="comments" id="comments">
</textarea>
<input type="submit" value="Skicka svar" />
</form>
```

This code will generate following form:

Namn		
Land		
Välj		~
🔵 Ja, jag godkänner	🔵 Nej, jag godkänner inte	
Kommentar		
Skicka svar		

Comment

Most form objects have a tied label but some don't. The slider below is missing one, making it especially problematic for VoiceOver users to understand what to select. For that reason, you need to make sure all form objects have a label tied to them so the label is presented when the form object has focus.

To do

• Ensure all form objects have a label tied to them.

Links to guidelines

<u>WCAG 2.0 - 1.3.1 (A)</u> <u>WCAG 2.0 - 2.4.6 (AA)</u> <u>WCAG 2.0 - 3.3.2 (A)</u>

FS70: Input fields in forms are identifiable through correct use of the autocomplete attribute

Background

Forms are a major problem for many users. This is particularly true for long and complex forms, and especially for users with cognitive disabilities. The simpler the form and the less the user has to fill in, the less likely they are to have problems. Many other groups also have particular problems with forms. Examples include users with writing difficulties and users with severe visual impairment.

The autocomplete attribute makes it easier to fill in form fields that are intended to contain frequently recurring information, such as name and email address. The user can enter the information once and let the browser save it for the next time the user enters the same information in other form fields. Autocomplete is used on form fields of different types such as text, email, number, password.

```
<form action="/subscribe.html">
Given name:<input type="text" name="gname"
autocomplete="given-name" />
Family name: <input type="text" name="fname"
autocomplete="family-name" />
E-mail: <input type="email" name="epost" autocomplete="email"
/>
```

Not applicable

```
<input type="submit" value="Subscribe" /> </form>
```

There are about 40 possible values to use in the autocomplete attribute.

In some situations it is not desirable for the browser to complete the form fields. Examples of such situations are when the user has to enter a one-time code when logging in to an e-service. In this case, the automatic completion can be turned off by setting the autocomplete attribute to "off" on specific form fields.

Assistive devices for people with cognitive disabilities can detect the autocomplete attribute in form fields and provide the user with a simpler and more understandable description of the information to be included in the form field. An example is when autocomplete is set to the value "tel" which replaces or supplements the form field's lead text with a phone icon.

To meet the requirement of this point, form fields listed in the W3C "Input Purposes for User Interface Components" list should have the autocomplete attribute set to the values specified in the list.

Input Purposes for User Interface Components

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.1 - 1.3.5 (AA) WCAG 2.2 - 1.3.5 Identify Input Purpose (AA) EN 301 549 - 9.1.3.5

FS80: Extended descriptions of a particular form field is tied to that specific field

Background

It is not always enough to have a common label text to explain to the user what, how, and why certain information in the form is required. When the need for an extended explanation arises, for example, to clarify the date formats, or why you ask the user to enter certain information, the explanation should be linked to the current form object.

The easiest way is to let the extended description be part of the label element. This is the most robust method. You can also use the wai-aria attributes arialabelledby and aria-describedby, however, this will cause some users to miss the information. Whether this is a problem or not, it must be sorted out on a case-bycase basis since it depends on the situation and on which users the system is addressing.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

FS85: The user does not need to fill in the same information more than once per visit

Background

Some users with cognitive disabilities may have difficulty remembering what they entered previously.

For example, each time the user uses a service to schedule their medical appointments, the user must rewrite certain information that the user provided in a previous step.

Information that has been previously entered or provided by the user and is required to be entered again in the same process is either: automatically filled in,

Nybrokajen 7 SE-111 48 Stockholm +46 8555 770 60 contact@funka.com www.funka.com/en

Not applicable

or available for the user to select.

Valid exceptions apply when it is:

- significantly important to enter the information again,
- the information is required to ensure security,
- or previously provided information is no longer valid.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.2 - 3.3.7 Redundant Entry (A)

FS100: The user can review, undo, or confirm information while performing important tasks

Background

It is common to perform important tasks digitally, such as transferring money or signing a contract. If the user accidentally makes a mistake, such as pressing the wrong button or misunderstanding information, the consequences can be significant.

Therefore, the user must be provided with assistance to ensure they do things correctly and avoid unnecessary problems. The best approach is to offer the user multiple safeguards. For example, they may be able to review a summary and confirm the information before it is sent, and have the option to undo the action.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines WCAG 2.0 - 3.3.4 (AA) WCAG 2.1 - 3.3.4 (AA) WCAG 2.2 - 3.3.4 Error Prevention (Legal, Financial, Data) (AA) EN 301 549 - 9.3.3.4 No errors found

FS120: The function of buttons is clear

Background

It is important that users understand what will happen when they click on a button. Therefore, buttons ought to be self-explanatory so the user understands their purpose. For example, a button named "OK" is not as obvious as a button named "Comment" or "Subscribe".

Comment

There are buttons whose function is unclear because they lack a name. The buttons only consist of icons and as they don't have a button text (visible or hidden) they lack a name.

This makes it difficult for VoiceOver users to understand their purpose. Below are two examples where the buttons are presented as only 'Button'. Either add a visible or hidden text to them providing them with a name.

Nybrokajen 7 SE-111 48 Stockholm +46 8555 770 60 contact@funka.com www.funka.com/en

FS130: Sections of forms are grouped

Background

Longer forms must be split and grouped. This makes it easier to see which parts belong together, both visually and with assistive technology. Grouping objects is done with fieldset and legend elements.

Example of a form with groupings:

```
<fieldset>
<legend>Delivery address</legend>
<label for="name1">Name:</label>
<input type="text" name="name1" id="name1">
<label for="adress1">Address:</label>
<input type="text" name="address1" id="address1">
<label for="ort1">City:</label>
<input type="text" name="city1" id="city1">
</fieldset>
</fieldset>
<label for="name2">Name:</label>
<input type="text" name="name2" id="name2">
```

× Fail

```
<lpre><label for="adress2">Address:</label>
<input type="text" name="address2" id="address2">
<label for="ort2">City:</label>
<input type="text" name="city2" id="city2">
</fieldset>
```

As soon as you have a group with radio buttons or checkboxes, you should use a fieldset and legend to give the group a common description. Without this, you could say in very simplified terms, it is like asking the user to answer a question without hearing the question first.

Comment

Some form objects are not grouped with their labels. This leads to two challenges for especially VoiceOver users. Firstly, the form object lacks a name and secondly, there are double navigation steps for each form object. In the example below, the label first receives focus.

Then, the next navigation step is on the checkbox, which lacks a name. Here, the checkbox and the label need to be grouped so that the checkbox gets a name and one navigation step can be avoided.

14:02		::!! ? 100

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

FS140: When an error is made, the user is made aware of this in a clear way

Background

If there is a possibility for users to make an error, errors most likely will occur. If this happens, it is important that the user is notified that something has gone wrong.

Provide a combined error message at the top

There are several different ways of showing that an error has occurred, however, to ensure as many users as possible understand this, most forms should offer a combined error message uppermost. This should clearly state:

- An error has occurred. We recommend using both a heading and an icon to state that it is an error message.
- Which errors have occurred? Ideally in a bullet list.
- Where the errors have occurred. Name the form objects where the errors can be found.
- If possible, also what the user should do to correct the errors.

Describe the error by the respective field

Provide clear and distinct error messages next to the invalid form fields, preferably combined with an icon. The error should also be described to the user here.

What more can I do?

It would be even better if you offer live validation so errors are detected while the user is completing the field. However, keep in mind that not all users will see this; it must therefore also be possible to submit the form even if the user has not corrected the errors. When the user has submitted the form, a combined error message as above should be shown.

It may also be worth linking each error message to the corresponding form field so that users do not have to search for them. No errors found but can be improved

Other types of error

Another example of errors that can arise is when the user tries to load a page that does not exist. Thus, the website must provide a clear error message that states that the page in question does not exist and give the user an opportunity to find the information in another way.

Comment

We have observed that an old error message, se image below, persists even when the user is in a new pop-up window where different information is requested. We have not been able to remove this message either.

Nybrokajen 7

16:12		🔁 89

Mitt konto Christer Janzon		
← Min Prof	ĥl	
Namn	Christer Janzon	1
E Andra na Förnamn Christer Efternamn Janzon Email finns	mn AVBRYT SPARA s redan	
Än	dra namn, Heading level <u>2</u>	

We believe that this problem is due to a bug. When we, as logged in users, try to change the email address, the system still shows the old email address, indicating that the change has not taken place.

When we then log out and try to log in again, it does not work. We suspect that this is because the email address was changed without any feedback. In addition, it is not possible to reset the password if the email address is incorrect.

We recommend that you implement a server-based validation to ensure that invalid email addresses cannot be saved.

This is not an accessibility issue and therefore this checkpoint is assessed as no errors have been found but it can be improved.

To do

- Make sure that error messages are displayed in the correct views.
- We advise you to implement a server-based validation to ensure that invalid email addresses cannot be saved.

Links to guidelines

WCAG 2.0 - 3.3.1 (A) WCAG 2.1 - 3.3.1 (A) WCAG 2.2 - 3.3.1 Error Identification (A) EN 301 549 - 9.3.3.1

FS150: Error messages are tied to their respective form field

Background

When error messages are inserted in a form and relate to a specific form object or a group with objects (for example a group of radio buttons), these must be tied to the form object or group. This is normally done by inserting the error message as part of the label or legend element.

This can possibly require that the error message is embedded twice, first to be displayed visually and second to be hidden in the existing instructional text. In this situation, it is advisable to conceal the visual error message for the tool and make sure the visual concealed error message is read. This can be done like this, for example:

HTML-code:

<label for="name">Name: Fail: You have omitted to enter your name</label>

<input id="name" type="text"> You have omitted to enter your name

CSS-code:

.concealed { position: absolute; left: -20000px;}

Naturally, it is preferred to enter the error message only once and visible for all users.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

FS170: All errors are described with text

Background

Error messages may contain pictures or even movies, but it is important that the error message is presented as text. Therefore, it is not enough to use an icon to highlight that something is wrong, this should always be explicitly stated in text form.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Tables

TB40: Table data is correctly coded with table code

Background

Ideally, you should always code tables with the correct table code.

CSS can be used to create tables that look like tables but are not coded as proper tables. There are also html5 roles and wai-aria attributes that can be used instead of traditional html code to create tables. However, these solutions do not always function properly for users with assistive technology.

For this reason, you should aim to always code tables with the elements table, tr, th and td.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Not applicable

Links to guidelines WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

TB50: Table headings are coded with the caption element

- Not applicable

Background

In order for users to understand a table easily, there must be clear table headings that are inserted correctly.

Use the caption element. It appears visually as a caption and at the same time gives the table a name. The name allows assistive technology to distinguish between different tables. The caption should briefly explain what information the table contains.

The caption element is placed at the top of the table at the same level as table rows (tr elements):

```
<caption>Flight prices Stockholm - Oslo</caption>

...
```

The image below shows an example of a table header.

	Flig	ht prices Stockholm - O	slo
MORNING FLIGHTS		AFTERNOON FLIGHTS	EVENING FLIGHTS
1500:-		1750:-	1750:-
150€		175€	175€
150\$		175\$	175\$

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

Not applicable

Background

In order for users to correctly interpret the content of tables, it is important that tables have clear column and row headings. These headlines should not only be visually clear, they must also be structurally correct with the th element instead of td elements. Th indicates that it is a table header cell, as opposed to the td element which indicates that the cell is a table data cell.

All table headings must be coded as th element.

The image below shows an example of column headers.

	MORNING FLIGHTS	AFTERNOON FLIGHTS	EVENING FLIGHTS
1	1500:-	1750:-	1750:-
	150€	175€	175€
	150\$	175\$	175\$

Flight prices Stockholm - Oslo

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

TB70: The scope attribute is used to indicate the direction of row and column headings when needed

Not applicable

Background

Table headings must be correctly linked with the data cells that are subordinate to the header. For simple one-axis tables, it is sufficient if the table header is identified as th. In tables with both row and column headers, this element must be supplemented with the scope attribute.

For column headings scope="col" should be used and for row headings scope="row" should be used.

Example table with row and column headings:

```
May
Morning flights
>1500:-
```

The image below shows an example of column and row headings.

Flight prices S	Stockholm - Oslo
-----------------	------------------

		APRIL	MAY
MORNING FLIGHTS	1500:-		1750:-
AFTERNOON FLIGHTS		1250:-	Sold out
EVENING FLIGHTS		No departure	1750:-

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

Not applicable

TB100: Complex tables are supplemented with the relevant code

Background

Complex tables must have more specific links between headers and data cells than simple tables. This can be achieved by giving each header an unique ID, and then referring to it in each cell using the header attribute.

In complex tables, logical categories can also be created using the axis attribute, which is used to group headings into common categories.

Examples of a more complex table where header cells and data cells are linked together:

```
<caption>Flight prices Stockholm - Oslo</caption>
Funka airlines
Fake airlines
April
May
April
May
Morning flights
1500:-
1750:-
1250:-
1750:-
```

```
• • •
```

The image below shows an example of an advanced table.

[FUNKA AIRLINES		FAKE AIRLINES	
[APRIL	MAY	APRIL	MAY
MORNING FLIGHTS	1500:-	1750:-	1250:-	1750:-
AFTERNOON FLIGHTS	1250:-	Sold out	1500:-	Sold out
EVENING FLIGHTS	No departure	1750:-	No departure	1750:-

Flight prices Stockholm - Oslo

If you have such a complex table, your first choice would be to divide it into several, simpler tables or to simplify the layout in another way so that you can manage with only scope to associate headings and data cells.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 1.3.1 (A) WCAG 2.1 - 1.3.1 (A) WCAG 2.2 - 1.3.1 Info and Relationships (A) EN 301 549 - 9.1.3.1

Script & WAI-ARIA

SW20: Use wai-aria in order to convey information that cannot be conveyed through the use of HTML and that benefits users

Background

Script imposes greater demands on assistive technology (AT) compared to only using html and CSS. This means that the risk of problems is increased. We therefore recommend that all complex functions be tested using the most widely used tools to ensure no unnecessary difficulties arise.

Examples of common problems include users with assistive technology not being able to focus on layers that are opened dynamically or cannot access search suggestions in a search form. This is because new layers and new information are often inserted in the bottom of the page structure and not nearby the object on which the user is focusing. Another common problem is that clickable areas are created with script instead of with links and buttons. Assistive technology does not perceive these as genuine links/buttons and therefore does not present them as interactive objects.

WAI-ARIA

WAI-ARIA is a specification of code that enables you to provide users of assistive technology with information about the website. For instance, with WAI-ARIA you can mark up dynamic content that makes it easier for assistive technology to manage and present the information to users.

We recommend using WAI-ARIA, but this needs to be done with caution. Do not use WAI-ARIA to rescue poor HTML. For example, it is not a good idea to use role="button" in a div element instead of using a proper button. Nor should you use WAI-ARIA without checking how it actually works for users; one common problem is inserting all the WAI-ARIA you can think of with the consequence that the tools become extremely vocal which is unnecessary.

Support for WAI-ARIA varies between the different versions of assistive technology and browsers. This means that for the time being, we recommend testing all dynamic solutions in practice with different versions of assistive technology, devices, and versions.

Information about WAI-ARIA (W3C website).

Not applicable

Test with assistive technology

To be certain that the script does not cause problems for users of assistive technology, you need to test this practically. Exactly which kind of assistive technology ought to be tested will vary depending on the solution. Nor is it simply a matter of sitting down with assistive technology and going through the service. You need knowledge of how users operate, how they use the assistive technology, what it feels like if you are visually impaired, etcetera. As a developer, for example, it is incredibly difficult to test a solution objectively as you have knowledge that the users lack.

We, therefore, recommend that you commission experts to do the testing.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 4.1.2 (A) WCAG 2.1 - 4.1.2 (A) WCAG 2.2 - 4.1.2 Name, Role, Value (A) EN 301 549 - 9.4.1.2

SW50: When new elements are added to the page, they are placed in the right order, both structurally and visually

Background

Nybrokajen 7

Occasionally, new content or new functions are added to a page without it being reloaded. When this happens, it is important that the new function or information appears in the right place both visually and structurally. If search results suddenly appear in a new area on the screen when the user starts writing in the search field, it is important that this area is clearly positioned visually where it belongs, and also in the right place in the structure so that assistive technology structurally present the information in the right place. It is best if this is done so that the new code is injected in the right places, for example:

SE-111 48 Stockholm +46 8555 770 60

```
<label for="sok">Sök:</label>
<input type="search" id="sok">
```

```
<!- Sökförslag läses in här --> <input type="submit" value="Sök">
```

There are also other ways to resolve this, such as sensing via script what the user is doing and switching the focus so that the effect is the same for the user. How this works in practice should also be tested with the most commonly used assistive technology.

One common problem is that a new area is positioned correctly visually, but ends up last on the page structurally. If a tool does not find something until after the page footer, there is a big risk that the user will not find it at all.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 1.3.2 (A) WCAG 2.0 - 2.4.3 (A) WCAG 2.1 - 1.3.2 (A) WCAG 2.1 - 2.4.3 (A) WCAG 2.2 - 1.3.2 Meaningful Sequence (A) WCAG 2.2 - 2.4.3 Focus Order (A) EN 301 549 - 9.1.3.2 EN 301 549 - 9.2.4.3

SW60: When new content or areas are loaded, focus is moved to them immediately

Background

If a covering layer or a new area opens dynamically on the page, it is important that the user focus is immediately directed onto this (unless it is a disturbance to the user). Examples of exceptions are search suggestions. The user's focus should not automatically be switched to the search suggestions as soon as they appear as this would be interruptive.

In the case of users that navigate through the keyboard, it is important that they come directly to the new layer or content without having to tab to the bottom of the page. If this is a form, the focus can be set on the first field, otherwise, the first tab

step should be after the link that opened the layer or resulted in the new area being read in, leading into the first link in the area.

Also bear in mind that the reading order must be correct for users with reading aids. When they continue to read downwards on the page from the link that opened the layer, reading should continue into the layer in question. You may need to test this with assistive technology.

If it relates to messages and dialogue boxes, WAI-ARIA roles for messages and message dialogues ought to be used. If it is a form, it ought to be the alertdialog role:

role="alertdialog"

Otherwise the alert role:

role="alert"

Information about WAI-ARIA (W3C website

Problems to view HTML-tag: u

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 2.4.3 (A) WCAG 2.1 - 2.4.3 (A) WCAG 2.2 - 2.4.3 Focus Order (A) EN 301 549 - 9.2.4.3

No errors found

SW70: When status is changed, users with assistive technologies are informed without focus being moved

Background

Updates in the interface that take place without the page being reloaded are particularly difficult for users with severe visual impairment to perceive. It may be that there is a change in an ongoing process, such as an updated queue on a website for the sale of concert tickets. It can also be about informing the user about how many search results a search has resulted in or validating errors in a form. It is problematic for the user to quickly move to another part of the interface to be able to read a status message before it is outdated or has been updated. Examples of status changes are:

- Information about the number of search results in a search
- A change occurs in a waiting application
- A change takes place in an ongoing process
- Errors occur in a form

When a status message is displayed on the screen, the user should be informed about it without having to move to another area on the page. Attributes role = "alert", aria-live, and aria-busy can be used to inform screenreader users of status messages displayed in other parts of the page than where the user currently is. This means that the user gets status messages, without having to search for changes or to update the page. Assistive devices for users with cognitive impairments can clarify, delay, or suppress status messages, depending on the user's preference.

```
Your search on
<strong><mark>accessibility</mark></strong>resulted in 384
hits
</h2>
</div>
```

Wai-aria attributes can be used in combination to make it clearer to users that a status update is particularly important. An example of this is to use the role = "alert" and aria-live = "assertive" attributes in messages that inform the user that they are being logged out.

The attribute aria-live has three modes that determine how high priority an update in an area should have:

• **Assertive** = An important message that must interrupt assistive technology as soon as possible.

• **Polite** = A less important message that should be presented as soon as the user pauses.

• Off = A message that does not need to be presented to the user.

This requirement does not apply to error messages in modal windows, the content displayed or hidden by foldable objects or content that requires user input. Thus, information about cookies does not count as a status message, because those require users to confirm their consent.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

<u>WCAG 2.1 - 4.1.3 (AA)</u> <u>WCAG 2.1 - 4.1.3 Status Messages (AA)</u> <u>EN 301 549 - 9.4.1.3</u>

No errors found

SW80: Content that is shown when an object receives focus is fully usable and reachable until the user shifts focus

Background

Users with magnifying tools only see a small part of the screen at a time, which makes it hard to overlook large areas. It's also problematic for users to find content that is outside the area currently enlarged. Users who navigate with a mouse or a keyboard and magnifying tools, that track mouse cursor and keyboard movement, must be able to move the focus without an area disappearing. This requirement applies both on hover with a mouse- and keyboard focus.

An example is mega menus, that is menus consisting of several levels and are displayed in large areas shown when the user hovers over the menu. They usually cover other content and disappear when the user's cursor moves outside the area. In order for users with magnifying tools to access all content, the user must be able to move focus freely within the area without closing it. The user should also be able to close the area in a simple way, for example with the escape key.

Areas not obscuring other content do not require a closing mechanism. An example is menus that, instead of being opened in a covering layer, are opened above the page's content which is moved down and placed below the menu. Also, error messages describing input errors need to have a closing mechanism. This requirement does not apply to modal windows or tooltips added with the title attribute as these are implemented in the browser.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.1 - 1.4.13 (AA) WCAG 2.2 - 1.4.13 Content on Hover or Focus (AA) EN 301 549 - 9.1.4.13

SW90: When a modal window is shown, focus stays in the window until it is closed

Background

If you use modal windows in your interface, it is important that all users can easily return to the main content without getting stuck in the modal window.

A common error when using modal windows is that the user can end up behind the window when using keyboard navigation, even though it is not closed. In other words, it is a requirement that users navigating with keyboards only are able to orient themselves within the window until the user has closed it.

When it comes to blocking access to the "background", we recommend using the aria-hidden = "true" attribute, which you can put as high in the structure as possible to include all content that is not in the modal window.

However, blocking the background for keyboard navigation is more demanding because you have to cancel the default behavior for each individual object, that is put tabindex = "- 1" on all links, buttons, and form objects, and whether it is relevant to other types of objects as well those that already have the tab index attribute.

Comment

We have encountered problems with VoiceOver in some types of modals. The problem is that the focus is not set within the modal when it is opened. While it is still possible to access the information in the modal, it takes extra time because the focus remains in a background layer. See images below.

× Fail

In this type of modal, as in the image below, we see no problems.

Mitt konto Christer Janzon	
← Min Profil	
Namn Christer Janzon	1
Ändra namn Förnamn Christer Efternamn Janzon AVBRYT SPARA Email finns redan	
Ändra namn, Heading level <u>2</u>	

To do

- Ensure that the focus is on the modal when it pops up.
- Also make sure that the focus is in the modal until it is closed.
- Keep in mind that when a modal window is closed, the focus should always return to the object that opened it.

Links to guidelines

WCAG 2.0 - 2.4.3 (A) WCAG 2.1 - 2.4.3 (A) WCAG 2.2 - 2.4.3 Focus Order (A) EN 301 549 - 9.2.4.3

SW100: Use aria-expanded for areas that can be expanded and collapsed

× Fail

Background

The aria-expanded attribute should be used for areas that can be expanded and collapsed. The attribute is set on the element that unfolds the area in question. Aria-expanded="false" indicates that the area is collapsed and aria-expanded="true" that it is expanded. For example, this could apply to an FAQ list where the answers are expanded when the user clicks on the question, or on a menu that expands into submenus.

This can apply to an FAQ list where the answers are expanded when the user clicks on the question or a menu that dynamically expands the next level.

Aria-expanded should only be used if this is done dynamically, i.e. not with a reloading of the page.

If the collapsible area is not directly adjacent to the element that uses ariaexpanded, a link between them may be needed. The link should then be created with the attributes aria-controls or aria-owns.

Example collapsed area:

```
<div class="faq-question">
    <button class="toggle" aria-expanded="false">
        When should I use aria-expanded?
        </button>
    </div>
<div class="faq-answer" style="display:none">
```

```
When an area can be expanded dynamically without
page reloading.
</div>
```

Example expanded:

Comment

We've only found a few buttons expanding and collapsing content, see example below. Buttons that expand and collapse content should describe their state through the code to the user, if it is expanded or collapsed.

In the example below, we see that there is no information that there are areas that can be expanded or collapsed.

```
13:58
```

Automatic events

AE20: New windows and covering layers are not opened unless the user has chosen to open them

Background

New windows and layers that partly cover the web page itself create problems for several groups of users. They create confusion and are often difficult to close. Users should therefore always be told that a new window or covering layer is going to be opened. Users should also be able to choose if a new window or layer should be opened.

This checkpoint is aimed at layers and windows that open automatically, for example, website surveys that open on top of the main window when the visitor opens a page or advert windows that are opened when the user accesses the website. Ordinary links that open new windows should announce this to the user, however, an evaluation of this information is made in checkpoint NL240 in the Navigation & links section of the audit.

Generally speaking, new windows and covering layers should not pop up without the user actively clicking on a link that clearly states what is going to happen. However, an option is to be to let the user accept this type of occurrence in browser settings.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.0 - 3.2.1 (A) WCAG 2.0 - 3.2.2 (A) WCAG 2.1 - 3.2.1 (A) WCAG 2.1 - 3.2.2 (A) WCAG 2.2 - 3.2.1 On Focus (A)

WCAG 2.2 - 3.2.2 On Input (A) WCAG 2.2 - 3.2.5 Change on Request (AAA) EN 301 549 - 9.3.2.1 EN 301 549 - 9.3.2.2

AE60: If automatic events or time limits are present, there is an option to pause or increase the time span

Not applicable

Background

In the case of time limits, users should be offered at least one of the following alternatives:

- Disable the time limit
- Extend the time limit. Users can personally decide how long the time limit should last and the max value should be at least ten times longer than the default value
- Expand the limit. For instance, by displaying a warning a few minutes before the time limit expires, the user has an opportunity to extend this

Users can, for example, have the option of disabling, expanding, or extending the time limit via a button that is displayed next to the time limit. Another alternative is to display a message a minute or so before logging out where the user can choose to extend the login time.

The time limit should always be related to the latest user activity that the system can recognize, not to the entire time of log in. If, for instance, the user goes from step 1 to step 2 in service, this should set the count to log out back to zero. If the nature of the time limit is such that the whole point of the feature would be nullified if it were postponed or changed, this can be an acceptable exception. Similarly, if the time limit is 20 hours or longer.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

AE80: If an area is updated without the page reloading, this should be indicated with WAI-ARIA

Background

Aria-live states how important changes are in the interface. For example, it decides whether or not assistive technology should interrupt the user.

Use the following values:

- Off: Use for something that is updated frequently, for example, stock price information.
- **Polite**: Use if a change only needs to be notified if the user is not doing anything important.
- **Assertive**: Use when something important happens that the user should be notified about as soon as possible.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

Frames

FR20: Every frame's purpose is described with the title attribute

Not applicable

Background

The purpose of each frame should be described in the title attribute. This information is presented by assistive technology for visually impaired users, and helps them understand whether they should go into the frame and read that web page, or continue on the current web page outside the frame.

```
<iframe
title="News from Funka"
src="funkanews.html">
</iframe>
```

If a video is shown in the frame, this should also be mentioned along with a brief description of the video's content.

```
<iframe
title="Video about accessibility on Youtube"
src="https://youtube.com/funka">
</iframe>
```

Frames whose only purpose is to collect statistics should be hidden both visually and for assistive devices.

```
<iframe
title="Statistics"
src="statistics.html"
aria-hidden="true">
</iframe>
```

Comment

Search functions

SF05: There is a search function, unless there is a specific reason to not have one

- Not applicable

Background

To meet the requirements of WCAG at level AA, there should be several different ways to find a specific page in the interface. Exceptions are pages that are steps in an e-service or process.

If you do not offer a search function, you must offer some other alternative way to find a page on the website. This could be a sitemap or an A-Z function.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 2.4.5 (AA) WCAG 2.1 - 2.4.5 (AA) WCAG 2.2 - 2.4.5 Multiple Ways (AA) EN 301 549 - 9.2.4.5

Documents & other forms of media

DM10: Background noise can be easily turned off manually or turned off automatically within 3 seconds

Background

Just as movements in the interface affect the visitor's ability to understand the information, background noise also affects the ability to concentrate.

For this reason, background sounds that starts automatically should stop after a maximum of 3 seconds. Alternatively, there must be a clear and easy method to stop the sound.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

<u>WCAG 2.0 - 1.4.2 (A)</u> <u>WCAG 2.1 - 1.4.2 (A)</u> <u>WCAG 2.2 - 1.4.2 Audio Control (A)</u> EN 301 549 - 9.1.4.2

DM20: Audio-only or video-only has a nearby text description

Background

Audio or video can be a good way to convey information. They provide the opportunity to explain complex relationships in a more understandable manner. However, there are instances where users may not be able or willing to access audio or video. This could be due to visual or hearing impairments, lack of equipment support, firewall restrictions, or poor connectivity.

Therefore, content in audio and video should always be clearly described. The level of detail in the description should be determined based on the importance of the content. The description can also include links to other parts of the interface where users can access corresponding information.

www.funka.com/en

Not applicable

Fail

Audio

When information is presented through an audio clip, the equivalent information must also be available in text form. There should also be a clear connection between the audio clip and the alternative text. This could include a transcription of the audio.

Video

For prerecorded video content, there should be a text version of the content clearly linked in proximity. The text version doesn't need to be an exact word-forword representation of the content, but it should provide equivalent information.

Comment

In general, we see your videos as complements to text. However, we encountered a problem with the video "Så här scananr du QR-koden" found under "Lägg till ny enhet". In the first step, there is only a video, see image below.

Så skannar du QR-koden

Nästa	
Steg 2 av 7	

The text that should accompany it is found under 'Hjälp' in the next step, see image below. If this text and video were on the same page, the video would be complement to the text.

Since they are not, we evaluate this criteria as failed.

Hjälp med att skanna en QRkod

- 1. Placera dörrklockan 10–15 cm ovanför mobiltelefonen.
- 2. Rikta in dörrklockans kameralins mot QR-koden.
- 3. För dörrklockan långsamt upp och ner över QR-koden för att underlätta skanningen.
- 4. Om QR-koden inte kan skannas kan du försöka dela den och öppna den på en annan enhet. Använd sedan dörrklockan för att skanna koden på den enheten i stället.

To do

• Make sure there is a clear instruction in the form of text near each video, just as you do in most places.

• Remember that even though your videos sometimes can explain instructions more clearly, text is still important.

Links to guidelines

WCAG 2.0 - 1.2.1 (A) WCAG 2.1 - 1.2.1 (A) WCAG 2.2 - 1.2.1 Audio-only and Video-only (Prerecorded) (A) EN 301 549 - 9.1.1.1 EN 301 549 - 9.1.2.1

DM30: Captions reproduce audio information in the pre-recorded video and audio clips

Not applicable

Background

If you have audio as part of a video or as an audio file, the content must be subtitled:

- For video, a strip of text synchronised with the audio is sufficient.
- In audio clips, it may be difficult to insert a text strip, but you can offer the user to read a text transcript of the audio information instead.
- If you have a music-only video, the name of the song or the fact that music is playing should be captioned to let the user know that nothing is being said.

What types of audio should be captioned?

The captioning should provide the information conveyed by audio. This means speech, but can also be other important sounds that contribute to the understanding of the content.

For example, the Swedish Transport Administration has an information film about supervised pedestrian crossings and how the sound signal is used by the severely visually impaired. If it is demonstrated via audio, it is important that the signals are also described via subtitles.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

DM40: Information presented as audio in live broadcasts is transcribed with captions

Background

Audio information in live broadcasts must also be captioned.

We recommend that you make a judgement as to whether it is reasonable to offer live subtitling in the case in question. However, to meet the requirements of WCAG at level AA, live broadcasts should be captioned.

NOTE: Certain types of content are exempt from the law on accessibility in digital public services, such as live broadcasts of time-dependent media.

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 1.2.4 (A) WCAG 2.1 - 1.2.4 (A) EN 301 549 - 9.1.2.4

DM100: Visual information in video is explained with audio

- Not applicable

Not applicable

Background

Video should be explained with audio, or audio description, so that a user who does not see the video is able to understand what is happening.

In many cases, this can be done by having a regular voiceover explaining what is happening, but in more complex films, a separate audio track may be needed for audio description.

Even in this case, you should make a judgement of reasonableness. But audio description is a requirement if you want to meet WCAG level AA.

Plain language & comprehensibility

US10: The user doesn't need to solve, remember, or translate any tasks to identify themselves

No errors found

Background

Some users with cognitive disabilities may not be able to solve puzzles, memorize things, or transcribe texts. Therefore, there must be an alternative way to identify themselves.

The alternatives can be:

- Another identification method that does not rely on a cognitive function test.
- A mechanism to assist the user in completing the cognitive function test.
- The cognitive function test is to recognize objects.
- The cognitive function test is to identify non-text content that the user provided to the website.

Comment

The interface fulfills the requirement in the checkpoint satisfactorily on the parts we checked. We assess the checkpoint as "No errors found".

Links to guidelines

WCAG 2.2 - 3.3.8 Accessible Authentication (Minimum) (AA)

US20: Instructions are understandable regardless of the user's ability to see or hear

Background

Everyone should have the opportunity to understand and manage instructions. For this reason, instructions must be understandable regardless of the user's ability to see or hear. Avoid formulations that only refer to colour, shape, direction, or sound, such as the "circle on the left."

Referring to a colour can sometimes be a good way to clarify something, but must be complemented by other information. Instead of "click the green button", the instruction could be "click the green button with the text 'Accept'". Then, in addition to the colour, there is also a text to help the user find the button.

Do not refer to objects that are "to the right" or similar. The reference cannot be understood by users who cannot see the interface. In addition, depending on the width of the screen in responsive interfaces, items may be placed elsewhere. Most instructional films assume that users can see and hear. Such films must therefore always be accompanied by a text version.

Comment

We found instructions that are not understandable if the user cannot see or hear. The exceptions are the instructions "Tryck på ögat för att ..." and "Tryck på rutan för att ...", se images below. In these cases, the user must see the element described in order to perform any action. This is further complicated by the fact that the elements referred to have no names.

If instructions and references are needed to read more, they must be understandable regardless of the user's visual ability. See the background text for more information.

US190: The primary language of each Web page can be programmatically determined

× Fail

Background

The primary language must be specified in the code on all pages. This makes it possible for assistive technology to determine the language in which the text is written and thus select the correct voice.

The primary language should be specified directly in the HTML element at the top of the page code.

In HTML5, the main language is specified with the lang attribute:

<html lang="en">

In XHTML, the primary language is stated with the attribute xml:lang="en". However, you should also add the older way of writing for backward compatibility (exception XHTML 1.1). Example:

<html xml:lang="en" lang="en">

Comment

Here we do not know what is going wrong but when we are in the app on an iPhone 11 and have Swedish as the system language, VoiceOver uses an English speech synthesizer English. When we do the same with our iPhone Xr, it works better because it is a Swedish speech synthesizer.

We also found instructions that are in English even though the language in most other places is in Swedish. We suspect this is a bug but it needs to be fixed.

To do

• Ensure that the language code of the app is included in all views so that a screen reader can recognize it and change to the correct language, regardless of what the user has set their phone to.

• Also make sure that all objects are in the primary language and that your instuctions are written in Swedish.

Links to guidelines

WCAG 2.0 - 3.1.1 (A) WCAG 2.1 - 3.1.1 (A) WCAG 2.2 - 3.1.1 Language of Page (A) EN 301 549 - 9.3.1.1

Not applicable

US200: Content in a language that differs from the primary language of the page is programmatically determined

Background

When language changes are made to the content, they should be programmatically determined as such.

For example, this could be a quote in another language, or that the page provides information in one language but the menus and site structure are in another. Such changes should be marked in the code.

This can be done on most elements, such as span, li, div, a and p. Individual terms and words do not need to be labelled.

In HTML5, language is indicated by the lang attribute:

This indicates that the paragraph in question is written in English. The attribute can be used on all HTML elements in HTML5.

In XHTML, language is specified with the attribute XML: lang = "en". However, this should be supplemented with the older way of writing for backward compatibility (exception XHTML 1.1). For example like this:

Comment

The interface does not use the type of solution that the requirement applies to. We assess the checkpoint as not applicable.

Links to guidelines

WCAG 2.0 - 3.1.2 (AA) WCAG 2.1 - 3.1.2 (AA) WCAG 2.2 - 3.1.2 Language of Parts (AA) EN 301 549 - 9.3.1.2

The Web Accessibility Directive

WAD10: The Accessibility statement is accessible and easy to find

Background

The Web Accessibility Directive requires all websites covered by the law to publish an accessibility statement. The accessibility statement should be easy to find on the home page or preferably accessible from all pages, for example in a footer. The link to this page should be named "Accessibility Statement."

The statement must be published in an accessible format and primarily target and support the end users of the website. It is also intended for the authority in charge of supervision.

Accessibility statement for apps

For a mobile application, the accessibility report must be published at least on the website of the responsible public actor, or where users can download the app. The statement can also be in the app, but it is not sufficient if it this is the only available location.

Content of the accessibility statement

The report must contain

- the name of the authority
- the name of the national law
- the name of the app/digital service/website
- compliance with legal requirements
- list of what is not compliant and
- description of and link to the feedback function
- link to the complaint function of the supervisory authority
- date of compliance assessment and the method used
- date of publication and updates of the statement
- the methodology used to create the statement.

Recommendations (not requirements) to include in the accessibility statement

 No errors found but can be improved

- link to the audit report.
- · description of how the organization works with accessibility
- formal approval of the statement from the responsible person in the organization
- date when the website was published
- date of last significant update or redesign
- specific communication service for people with disabilities.

Comment

The criteria has the same assessment on Android as on iOS.

You are not subject to the requirement to have an accessibility statement and cannot be failed on this point. However, we think that there are great advantages in producing an accessibility statement that highlights any shortcomings that exist in the app and when it is planned to address these shortcomings and where users can contact for feedback.

WAD20: The feedback function or a link to such is found in the accessibility statement

Background

Users should be able to inform about any accessibility issues through a direct feedback to the person responsible for the website.

Design of the feedback function

Users should be able to report errors in a feedback function. So that the visitor can contact the website owner and:

- report accessibility issues
- request accessibility of content exempted under certain sections of the law.

Please describe how the feedback function is handled and provide information on your normal response times. You can also provide the contact details of the department or person responsible for the website and feedback management.

Not applicable

Not applicable

WAD30: A link to the supervisory authority's notification function can be found in the accessibility statement

Background

In cases where the visitor has provided feedback to the website owner about lack of accessibility but has not received a response, there should be a possibility to register their complaint with the supervisory authority.

The accessibility statement should describe how complaints are handled and provide a link to the complaints function of the supervisory authority.

WAD50: Documents are accessible

Not applicable

Background

Accessibility of various documents, such as PDF documents, is important and must not be forgotten. In this point we audit at least one document per service/main entrance and some randomly selected ones.

The image below shows an example of what an automatic accessibility check of a pdf document might look like when using the program Adobe Acrobat Pro.

Tillgänglighetskontroll

```
